PILOT GUIDE

# Try ZYVORA in an afternoon.

Install the demo on a Mac or Linux machine (Windows runs through WSL 2 and has not yet been verified on a real PC), and decide what a pilot should prove. Synthetic data only.

## 1. Install the demo (about two minutes)

- You need a container engine (Docker, Docker Desktop, OrbStack or Podman), about 3 GB of disk and 2 GB of memory. If there is none, the installer offers to set one up and asks first.
- One command from the public release page installs and starts a demo with built-in sign-in, no passwords and synthetic patients, listening on that machine only. The installer opens your browser when it is ready.
- Check it with the installer's own test command. Remove it cleanly with its uninstall command. Backup, restore and upgrade (which rolls back on failure) are included.

## 2. What to try

The demo comes with six synthetic patient stories: signed notes, allergies, prescriptions, a chest X-ray report, a note awaiting signature and a nurse conversation. Sign in as different roles and try:

| | |
|---|---|
| **A clinic day** | Register a patient, book, check in, consult, prescribe, sign. Watch the audit trail record each step. |
| **The laboratory** | Order, collect, enter a result, have a second person verify; see a critical result escalate until someone acknowledges it. |
| **Pharmacy** | Dispense part of a prescription and see the balance owed. Mark a drug controlled and watch it refuse to move without a witness. |
| **The money** | Raise an invoice, capture a missing charge, open a claim case and its checklist. |
| **AI, off then on** | An administrator switches AI on (Insights) and each assistant on (Setup). The development stand-in is badged as such and says nothing about any model. Try a draft and see that it needs your review. |

## 3. Decide what a pilot should prove

- Which two or three workflows would you move first, and who signs off the thresholds (lab targets, reference doses, payment terms)? None ship; your leads set them.
- Which identity provider will you use? Sign-in is standard OpenID Connect, tested against Keycloak.
- Which systems must connect (analysers, a hospital information system, a viewer)? Name them, and ask for the integration status sheet.
- If you want AI, which cases from your own hospital can clinicians write to measure it? That, not a vendor figure, is the evidence.

Before real patient data. ZYVORA is not certified or attested against any regulation and nothing in it is a compliance claim. Read the published gap list, run your own privacy impact assessment and arrange an independent security review first.
